Atty. Docket No.: 44151-00005USPT

Please amend the subject application before examination as follows:

In the Specification:

e en e

In compliance with 37 C.F.R. § 1.121(b)(3), please replace the specification

submitted on October 26, 2001 with the substitute specification included hereinbelow.

The substitute specification includes no new matter in compliance with 37 C.F.R.

§ 1.125(b). Also enclosed as Attachment "A" is a marked up version of the substitute

specification.

[1001] This patent application claims the benefit of U.S. Provisional Patent

Application Serial Number 60/279,335 filed March 28, 2001.

Field

[1002] The present invention pertains to a computer hosting service; more

particularly, the present invention describes a computer hosting service providing a

platform system and method where computer clusters serving as a platform are

configured automatically and have a system of virtual environments (VE) integrated with

a distributed file system.

Background

[1003] The task of providing a computer hosting service arose with the onset of

linking computers together. The idea of providing a set of application services by a

particular server to outside personal computer users arose with the creation of shared

access centers. Generally, these shared access centers consisted of mainframe computers

(term described in http://www.pcwebopedia.com/TERM/m/mainframe.html) which

allowed user access to some services, such as booking offices.

Patent Application Inventors: Alexander Tormasov et al. Atty. Docket No.: 44151-00005USPT

[1004] The rapid growth of the Internet and the need for remote access to servers profoundly increased the demand for a computer hosting service. The growing need for quality and efficiency of both Internet access channels and servicing computers led to the rapid growth in the creation of data centers and the services they provide.

[1005] The provision of remote computer hosting service is based on the clientserver concept. (Operating Systems: a design oriented approach, Charles W. Crowley. Irwin. 1997. ISBN 0-256-15151-2.) The problem of shared access to files, for instance, can be efficiently solved using a client-server model. Traditionally, the problem of shared access to files was dealt with by providing a corresponding service to one of the network computers, e.g., by means of a file server. When a file server was used, software installation was required to allow the other computers to work with files located at the corresponding server. This functionality was achieved by copying the files locally or by emulating access to the network files for files located at a virtual local disk. For instance, the DOS software developed for the operating systems of IBM PC compatible computers has been organized in exactly this way. Client software, properly connected to both the network and the corresponding file server, displayed the so-called network drive. (Distributed Operating Systems, Andrew S. Tanenbaum, 1994. Prentice Hall. ISBN: 0132199084.) As a result, the locally launched software of a client will work with remote files in the same manner as if the remote files were placed on a local hard drive.

[1006] More sophisticated problems occur when the server and services are spaced far apart and linked together by the Internet global network, e.g., files at a server to which access is provided by special network protocols such as the http-World Wide Web service-protocol (Network Working Groiup "Request for Comments: 1945

r 2

Atty. Docket No.: 44151-00005USPT

Hypertext Transfer Protocol -- HTTP/1.0".) These protocols are intentionally tailored to

function in a distributed client-server network with connections which are looser than

those found in a local network such as described above.

[1007] Servicing such a protocol requires WWW server installation with a stable

Internet connection plus regular computer and service functioning. Such services require

substantial capital investments and are primarily available in the data centers. Only the

professional computer centers can render safe and dedicated Internet access lines, surplus

power supply, cooling, and fire/damage protection.

Typically, data center customers receive the following services and

equipment:

•

dedicated data center-owned computer with network access fully operated by the

customer

installation of the customer's computer in the data center, i.e., collocation service;

and

a data center computer partially operated by a customer for use of services

provided at the discretion of the data center.

[1009] The last service mentioned above may occur if the data center has

specially trained personnel and software. Usually a separate department or an

independent company carries out this service while a data center simply provides all the

necessary equipment. Today, such companies frequently provide the "web hosting" or,

in other words, permit the providers' web servers to be filled with independent contents.

(Building a UNIX Internet Server, George Eckel. 1995. New Riders Publishing. ASIN:

1562054945.)

Atty. Docket No.: 44151-00005USPT

[1010] Traditionally, web-hosting companies render their own web-servers as they are, without any configuration modifications. Installation of the so-called scripts or executable CGI files (*The Common Gateway Interface*. http://hoohoo.ncsa.uiuc.edu/cgi/overview.html), written in a Perl-type interpretive language, may present certain difficulties. The scripts should be executed at the server together with instructions received from users. Usually the scripts are used for dynamic

generation of web page content. Most active servers have long been generating almost

all of their pages by this "on-the-fly" technique. However, mutual utilization of these

applications may cause a number of difficulties, including versions of language

interpreters, web-servers and web-server configurations, incorrectly written applications,

and associated server failure, plus loss of security and unauthorized access to data.

[1011] Under the prior art scheme described above, users get access to the shared server but are not able to modify the shared server configuration to their preferences and needs (See Figure 1). Scripts that are launched in the common environment for all users and any script with the slightest problem immediately influence

every participant of the scheme.

[1012] The set of required uses goes beyond web-hosting to include such widespread services as e-mail and ftp services of electronic mail and file access. Difficulties arising under their functioning are similar to those of the www service described earlier. Moreover, users often prefer access to a separate computer connected

to the Internet, i.e., via telnet or secure shell connection.

[1013] In today's market, Application Service Providers (ASP) represent another class of hosting services that are in demand. Usually, Application Service Providers

Atty. Docket No.: 44151-00005USPT

provide shared access to a shared application such as a database, which is installed and

administered by the provider's system engineer. (Beginner's Guide to ASP.

http://www.aspstreet.com/archive/d.taf/sid,14/id,715.) User access is restricted to the

database alone. Access to office applications, for example, is practically impossible as

their installation implies that there is only one user. Security of data access is yet another

problem.

[1014] Presently available services are generally limited to web/email/ftp servers

or services which allow users to install a dedicated computer independently and then to

be responsible for its administration.

[1015] Applications-emulators of an operating system may be potentially used

for personal remote computers. The series of operating systems, the latest one called

"z/VM", applied in IBM systems software, appears to be among the first of such emulator

products. When applied, the users receive a full-sized computer with emulating hardware

and the opportunity to install their own version of an operating system. (z/VM V4 R2.0

General Information Manual. http://www.vm.ibm.com/pubs/pdf/hcsf8a41.pdf.) Both

hardware and software in this case must meet a high standard of quality and are

consequently very costly. Only companies with qualified personnel and adequate start-up

capital for the initial system installation choose this option.

[1016] Until recently, similar systems with the much cheaper IBM PC

compatibles have not met the technical requirements. Nearly complete emulation of

hardware by software and the functioning of two kernels of operating system (one on top

of another on the same computer) has resulted in a small scalability with high

maintenance overhead. (VMware Workstation User's Manual.

Atty. Docket No.: 44151-00005USPT

http://www.vmware.com/pdf/ws30 manual.pdf.) Users working in such an

environment typically become dissatisfied with the resources consumed and the emulator

performance proportion. An insufficient level of hardware specialization has made these

methods impractical with the IBM PC architecture for mass customer servicing.

[1017] Nevertheless, the problem of providing high quality, efficient computer

hosting services persists and remains unsolved. There is a need in the art for improved

unification and simplification for both users and administrators. For simplicity and to

ease hardware emulation, a small set of options, available at the operating system inside

the emulator, would be preferable. The installation process and system support should be

simplified. Maintenance and Administration of the underlying operating system should

be streamlined and require fewer resources. Such virtualized pseudo-hardware should be

less diverse and require less maintenance than real data center hardware. Such a system

should narrow support to highly unified configurations in order to simplify the work of

system engineers and administrators and allow the development of efficient control and

monitoring software for the entire complex.

[1018] Additionally, there exists a need to minimize the users' physical access to

the network and computer hardware. This is another big problem for data centers.

Today, client service at data centers requires that clients have extensive physical access to

their own computers. Thus, data center management is forced to use high-end control

and access-providing technologies that require expensive and not necessarily effective

security measures against physical damage. Such measures include secured vaults, anti-

bombing devices and protection against access to data center equipment and data center

customers' computers. However, such a need for frequent hardware access is often

Atty. Docket No.: 44151-00005USPT

caused by the outdated computer organization employed. User access and physical

contact with hardware is inevitable when users alone can get the computer reloaded by

means of special repairing disks. What is needed is a system and method which does

more than simply reducing such contacts but also completely eliminates procedures of

this kind and vests rights of hardware interference with the data center personnel only.

SUMMARY

[1019] This invention is directed to a system and method for utilization of

computer clusters with automatic configuration and virtual environments that are

integrated with a distributed file system as a platform for providing hosting services. The

virtual environment of the present invention emulates no hardware and is essentially a

personal protected machine with an independent operating system that functions as a

separate workstation or server.

[1020] The virtual environments on the same computer are completely isolated

from each other, yet are highly unified, with simple, well-formulated, and economical

installation and maintenance. The system permits all private data from every virtual

environment to be visible at every participating computer. Thus, all virtual environments

may be restarted at any computer of the cluster. Additionally, every virtual environment

may be easily moved from one computer to another.

[1021] In the present invention, a set of virtual environments is launched and

several computers are combined with a distributed file system and a control center into a

sharable cluster. End users are linked to their virtual environments via the Internet.

Administration is carried out through the control center by means of the Internet or local

Atty. Docket No.: 44151-00005USPT

network. Installation, repairs, and backup are accomplished simply and efficiently.

Cluster functioning is primarily accomplished without administrator participation. Thus,

the present invention promotes efficient control and monitoring of the entire system by

the data center personnel and minimizes the users' physical access to the network and

computer hardware. Such controlled access and protection of data integrity enhance

system security and reliability.

BRIEF DESCRIPTION OF THE DRAWINGS

[1022] A better understanding of the hosting service providing platform system

and method of the present invention may be had by reference to the drawing figures,

wherein:

FIGURE 1 is schematic of the traditional architecture used for work organization

of computers and users,

FIGURE 2 is a schematic of the virtualization of an operating system technique,

FIGURE 3 is a schematic of the usage of a distributed file system for data storage

of virtual environments,

FIGURE 4 is a schematic of the general configuration of a cluster and its

interaction with end users, and

FIGURE 5 is a schematic illustrating the installation of virtual environments by

means of the distributed file system in case of a cluster node failure.

Atty. Docket No.: 44151-00005USPT

DETAILED DESCRIPTION OF THE EMBODIMENTS

[1023] As shown in Figure 1, the traditional architecture 100 used for work

organization of computers and users included a customer environment 20 consisting of

network access 30, hardware 40, operating system 50, and application software 60. The

environment 20 was accessed by multiple users 10 and the architecture was duplicated

for every customer environment.

[1024] In lieu of this configuration, the present invention suggests the utilization

of a virtual environment for providing hosting services.

[1025] A virtual environment is a fully functional virtual machine that may be

easily run by users and operated by an operating system. In contrast to IBM, VMware,

and other similar software, virtual environment emulates no hardware. Every virtual

environment represents a personal protected machine with a root operating system 110

and root application software 120 that works as a separate workstation or a server as

shown in Figure 2. Several virtual environments may function at one and the same

computer at the same time. The OS virtualization layer 130, called HSP complete

virtualization layer, allows users to access a virtual environment 140 which represents

their personal server with super-user rights that allow software installation, addition of

users, etc. Virtual environments of one and the same computer are completely isolated

from each other. A user of one virtual environment is unaware of other active virtual

environments and their inner processes.

[1026] Inside a virtual environment, users are able to install any software

supported by the underlying operating system, such as their own web-servers with CGI-

scripts and dynamic modules, email servers, ftp servers, RealAudio/Video servers, X-

Patent Application

Inventors: Alexander Tormasov et al. Atty. Docket No.: 44151-00005USPT

servers with remote access and sshd servers. They also may build their own firewall, use

programs compiled from the source code, and install practically any application. In other

words, users are able to do whatever they prefer at a separate computer connected to the

Internet. Thus the system of virtual environments substantially overlaps the regular set of

web-hosting services.

[1027] From the point of view of users and system administrators, all the virtual

environments constitute a set of highly unified remote computers with simple and well

formalized maintenance where installation is reduced to a minimum. High commonality

results in highly efficient control tools, which enables the management of a great number

of similar virtual environments. From the users' perspective, virtual environments

decrease training time and reduce routine operation requirements.

[1028] Several computers with a set of installed virtual environments constitute a

standardized environment able to provide hosting services to end-users in terms of virtual

environments.

[1029] In the present invention, a distributed file system is used and all the

computers are connected in such a way as to make private data 152 from each virtual

environment 140 in the common files area 160 visible at every participating computer, as

shown in Figure 3. Private data 152 for a particular file is stored in the common files

area 160 in the virtual environments private data areas 150. This private data 152 is

visible from every cluster node and is utilized to restart a virtual environment if

necessary. This scheme raises the fault-tolerance level in case of software or hardware

failure as all the virtual environments may be easily restarted at any computer of the

cluster. The distributed file system makes the data from the failed computer available to

Atty. Docket No.: 44151-00005USPT

users. Additionally, the distributed file system allows successful hardware maintenance

as every virtual environment may be easily moved from one computer to another, i.e.,

virtual environments from a computer under scheduled maintenance can be moved to

another machine almost invisibly to users.

[1030] In the present invention, a set of virtual environments 140 is launched and

several computers are combined with a distributed file system 180 and a control center

190 into a sharable cluster (See Figure 4). A cluster consists of a control center 190 and a

set of hardware nodes 200 where virtual environments 140 have been launched. End

users 10 are linked to their virtual environments 140 via the Internet 210. Administration

is carried out through the control center 190 by means of the Internet 210 or local

network. Such a cluster may provide efficient HSP with cost-effective support and a high

level of scalability.

[1031] Initial installation comes as another challenge for the administration of

any multi-computer system. As a rule, initial installation of any computer requires

manual intervention by the administrator. This makes the installation of multiple

computers a difficult and resource-consuming operation. A computer used as a platform

to launch virtual environments is installed automatically in full from a corresponding

server or a CDROM. After the fully automatic installation has been completed to the

local disk of a newly introduced computer, the computer platform is available for

effective control from data center control tools, is connected to the distributed file

system, and becomes registered as ready for servicing (i.e., ready for launching new

virtual environments). If a server is to be turned off for scheduled maintenance, the

server first informs the control center, and the control center moves the launched virtual

Atty. Docket No.: 44151-00005USPT

environments to an alternative server. It is only after this is accomplished that the server

is disconnected and the center is notified of the disconnection. Thus, cluster functioning,

for the most part, is accomplished without an administrator taking part in the process.

[1032] In the past, the absence of remote repairing instruments made an

administrator's personal interference indispensable when an operating system software

configuration at a dedicated or displaced computer was damaged. Such is not the case for

a cluster configuration associated with virtual environments. Even a failed software

configuration of a particular virtual environment does not require a user's physical

presence.

[1033] Files of a failed virtual environment 220 are accessed from a newly

created virtual environment 240, allowing a user 10 to repair a failed software

configuration as shown in Figure 5. This is possible because failures of this type do not

influence the other virtual environments 140 nor underlying operating system 50.

Because the private data 152 of the virtual environments 140 is accessible from every

hardware node 200, switching off any cluster node from virtual environment servicing

may be backed up by neighboring cluster nodes.

[1034] The disclosed system and method has been disclosed by reference to its

preferred embodiment. Those of ordinary skill in the art will understand that additional

embodiments of the disclosed system and method are made possible by the foregoing

disclosure. Such additional embodiments shall fall within the scope and meaning of the

appended claims.
